01

# Panel Layers

# Panel buildup from inside

## Steps

- » Thin 5 mm wood fibre boards applied after roof is finished
- » 2 layers of clay base coat
- » Final clay plaster

## Note

- » Clay can be applied directly on the straw
- » A mesh should be used in the base coat
- » The first base coat will crack due to natural contraction during drying

## Alternatives

- » Any boards (plywood, gypsum boards etc.) that have a higher sd value than clay can be used inside.
- » In this case use strips of wood instead of thin wood fibre boards

# Panel buildup from outside

## Steps

- » Panels are covered immediately with an airtight but diffusion open membrane
- » All connections need to be taped (60 mm wide tape)
- » Plywood strips secure the membrane in place

## Note

- » Always ensure there is overlap
- » Be careful to leave enough membrane to connect to the inside membrane

## Careful:

- » Never use an inside membrane on the outside! Any membrane used inside has a higher sd-value and is not suitable.

02

# U-Values

# U-values calculation: Based on Technical Certificate

- » In the Technical Certificate, the thermal resistance for straw is defined at 0.056 W/mK. For wood 0.13 W/mK is used.
- » In a U-value calculation where there is 10% wood and 90% straw (average for a complete wall), the resulting U-value is:  $U = 0.145 \text{ W/m}^2\text{K}$  or  $R = 6.9 \text{ m}^2/\text{WK}$
- » This value is for straw panels without clay plaster or wood fibre board.

## Note

- » In Austria, straw insulation is officially used with a better value of 0.05 W/mK.

## Characteristics

- » Final U-value depends on thickness of wood fibre board

## Available upon request

- » Excel calculation template for U-value calculation

## U-values with wood fibre board:

**60 mm** -  $U = 0.121 \text{ W/m}^2\text{K}$

**100 mm** -  $U = 0.110 \text{ W/m}^2\text{K}$

**140 mm** -  $U = 0.100 \text{ W/m}^2\text{K}$

## Calculated layer values:

0.700 W/mK for clay (30 mm)  
0.056 W/mK for Straw (400 mm, 90%)  
0.130 W/mK for Wood (400 mm, 10%)  
0.046 W/mK for wood fibre board  
1.400 W/mK for plaster (7 mm)

03

# Airtightness

# Airtight, but open to vapour

- » The airtight layer is on the outside of the straw. We use an airtight layer that is completely permeable for humidity.
- » The membrane is mounted immediately during construction, and protects the straw against rain.
- » The fibres in the wood fibre board help to move humidity from the airtight layer to the outside surface where it can evaporate.
- » The wood fibre board further protects the straw from moisture damage from the exterior.

## Note

- » Always use airtight membrane open for vapour -  $S_d < 0.2 \text{ m}$  (equivalent of 20 cm air gap)
- » No leakage of moist air means no damages from condensation
- » Verify airtightness with a Blower Door Test

# Airtight & rain protection during construction

## Note

- » Membrane can protect walls against rain until you mount the wood fibre boards
- » Saves time otherwise used for covering the building
- » Airtight membrane should be applied the same day the EcoCocon panels are assembled
- » Attach membrane with plywood strips to fix well against wind

## Tip

- » Cover also the window openings - you can cut them open later

# Airtight, but open to vapour

- » Humidity passes through construction by difference of temperature and always from warm to cold side
- » This transport is very slow compared to transport by Airflow
- » Airflow is the main reason why condensation might occur and can be very damaging to the structure
- » The materials on the outside have to be completely diffusion open
- » Natural materials (wood fibre, cellulose, straw) are good at transporting moisture due to fibre content

## Note

- » View WUFI calculation reports for detailed information

# Danger of damages by leaking humid air flow

In a cold climate, warm and humid interior air can condense in the construction, if there is an air leak in the envelope.

A properly installed airtight membrane and a Blower Door Test helps to ensure there are no such leaks.

Even a small leak can produce a lot of humidity, up to 360 g per day for a gap 1 mm wide and 1 m long.

## Note

- » Careful detailing of all connections
- » Identify leaks with a BDT during construction
- » Use special elements to ensure airtight connection for cables

Up to 360 g  
water escapes  
per day

Heat loss  
due to  
airflow

**Outside:**

20°C

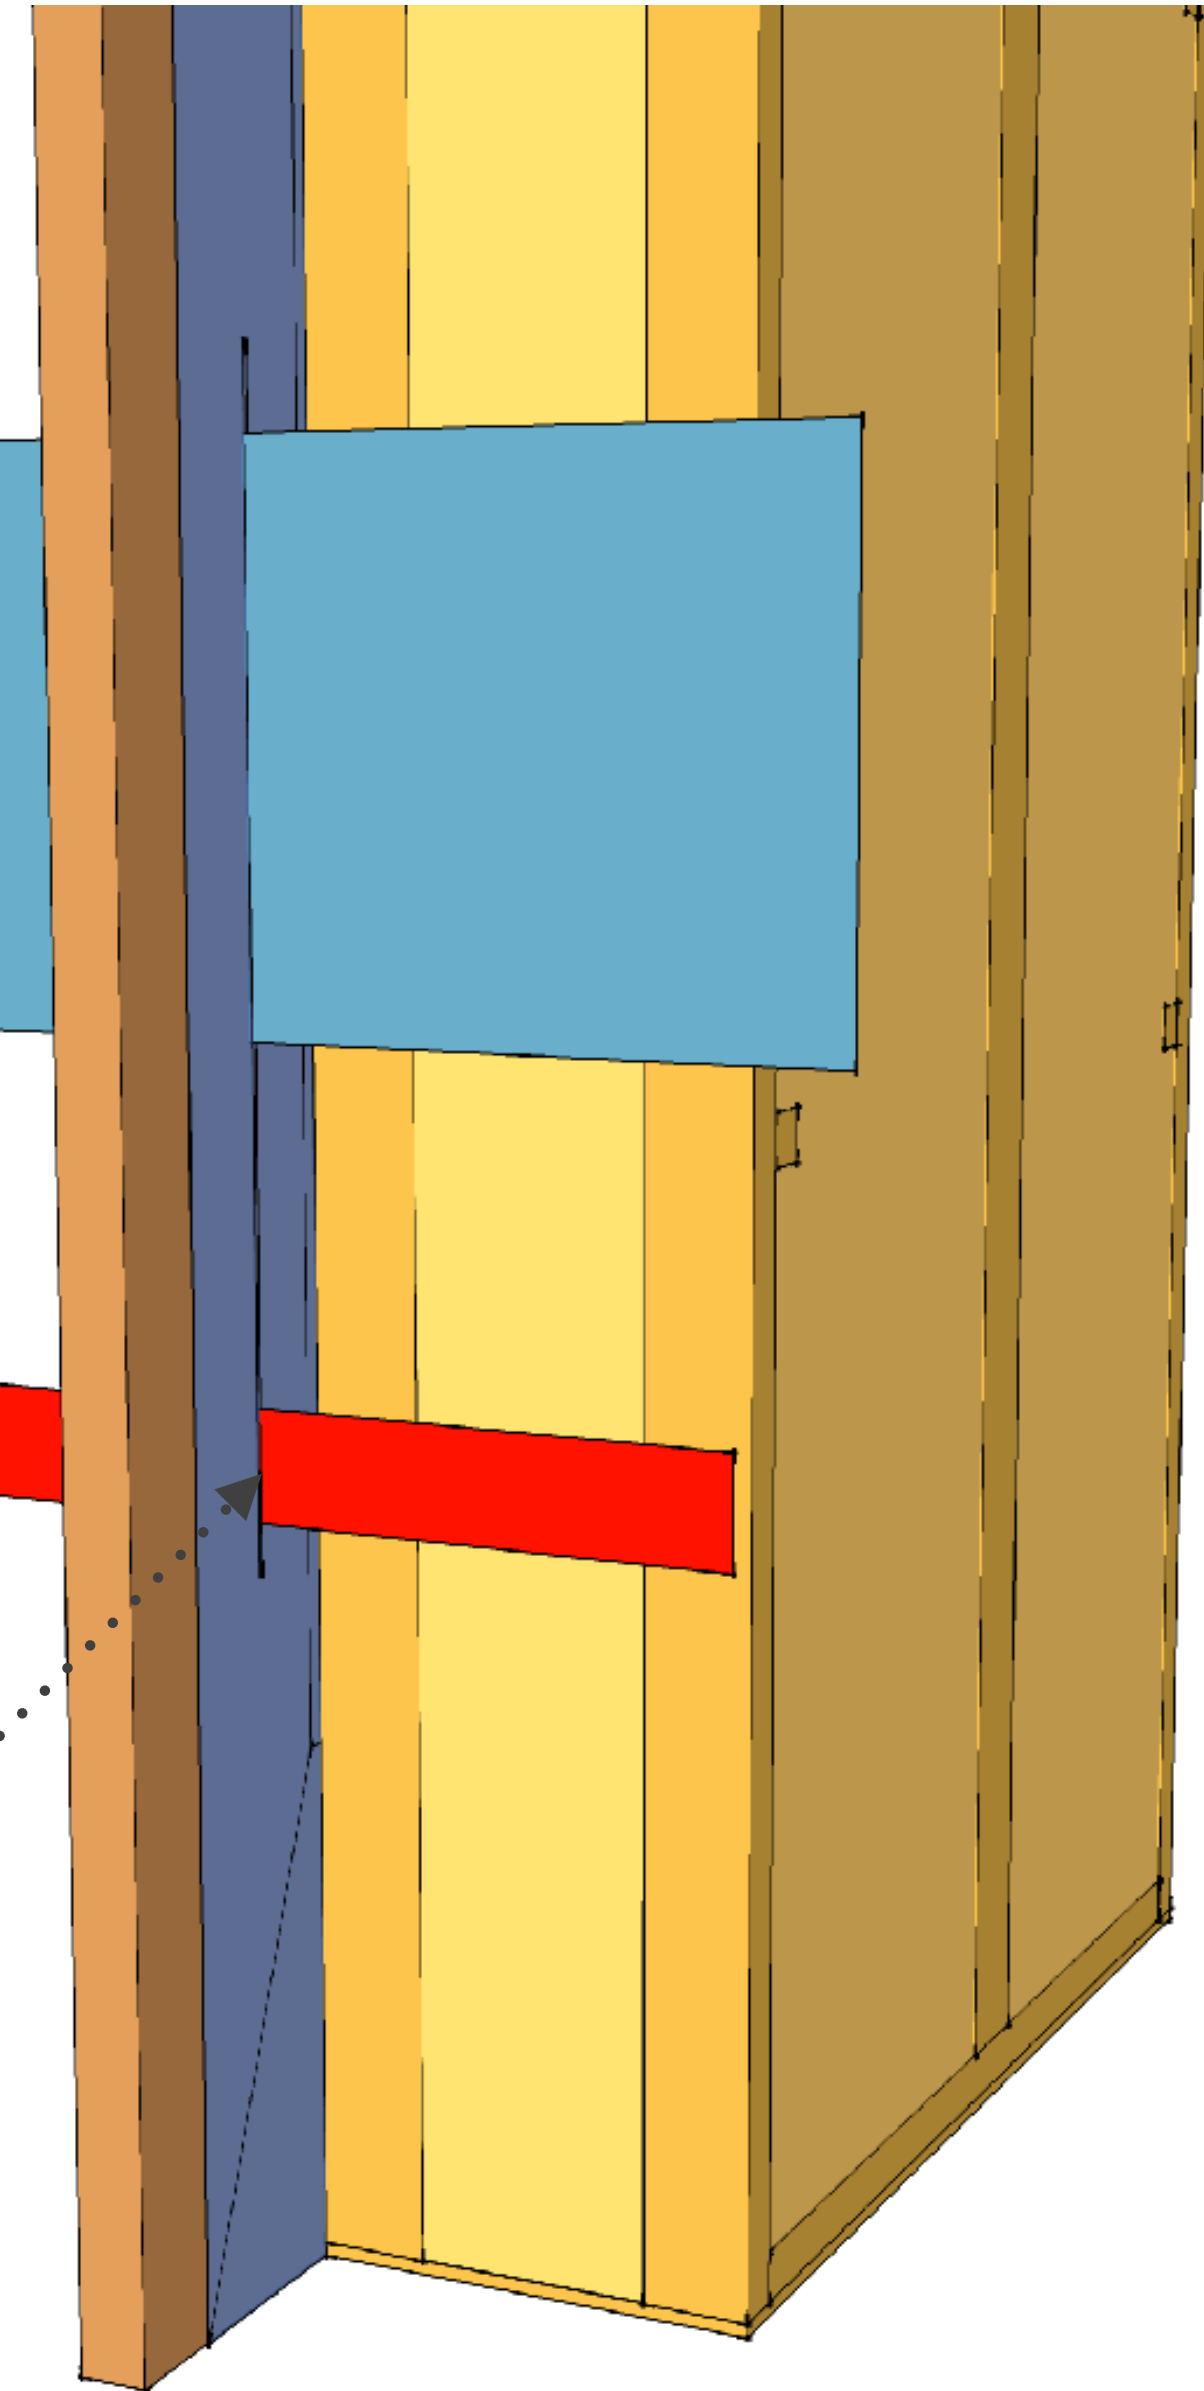

80% real.  
humidity

Gap 1 mm x 1 m

**Inside:**

20°C

50% real.  
humidity

# WUFI Calculation

# Airtight layer: WUFI Calculation

The airtight layer has been verified by German Building Physicist Brandhorst using WUFI.

For the cold climate in Vienna a dynamic calculation over several years has been made.

## Note

- » The system should work for all climates except areas with very long extended winters and permafrost - above polar circle.
- » The system works also for hot and humid climates. Miami was calculated as an example.
- » Airtight construction and verification by Blower Door Test is absolutely necessary!

# Airtight layer: WUFI Calculation

Wood fibre boards move the excess humidity away from the membrane very efficiently

## Characteristics

- » Although there is an increase in humidity in cold months, this is inside the limit of 25% water content in the wood fibre board
- » Wood fibre boards dry out very quickly during summer

Wood fibre insulation board:
